

Day 2 – Python Unit-1 Notes

Variable

Definition: A variable is a named memory location used to store data that can change during program execution.

Data Type

Definition: A data type specifies the type of data stored in a variable.

1. Primary: int, float, double, char, Boolean, string.
2. Derived: Array, Pointer, Function.
3. User-defined: Union (Shared Memory), Structure (Separate Memory).

Identifiers

Names given to variables, functions, classes, etc. Must start with a letter or underscore, cannot start with numbers, cannot contain spaces or special characters (except underscore), and cannot be a keyword.

Keywords

Reserved words in Python with special meanings. They cannot be used as variable names or identifiers.

Literals

Fixed values in a program: Numeric, String, Boolean, Special (None).

Separators / Punctuation

() , [] {} , ; , ,
